Multiple common and rare variants of \textit{ABCG2} cause gout

\textbf{ABSTRACT}

\textbf{Objective} Previous studies have suggested an association between gout susceptibility and common dysfunctional variants in \textit{ABCG2} with elevated urate transport function. Therefore, we investigated the effects of rare \textit{ABCG2} variants on gout susceptibility.

\textbf{Methods} We sequenced the exons of \textit{ABCG2} in 480 patients with gout and 480 healthy controls (Japanese males). We also performed functional analyses of non-synonymous variants of \textit{ABCG2} and analysed the correlation between urate transport function and scores from the protein prediction algorithms (Sorting Intolerant from Tolerant (SIFT) and PolyPhen-2 (Polymorphism Phenotyping v2)). Stratified association analyses and multivariate logistic regression analysis were performed to evaluate the effects of rare and common \textit{ABCG2} variants on gout susceptibility.

\textbf{Results} We identified 3 common and 19 rare non-synonymous variants of \textit{ABCG2}. SIFT scores were significantly correlated with the urate transport function, although some \textit{ABCG2} variants showed inconsistent scores. When the effects of common variants were removed by stratified association analysis, the rare variants of \textit{ABCG2} were associated with a significantly increased risk of gout (OR=3.2, p=6.4×10^{-3}). Multivariate logistic regression analysis revealed that the size effect of these rare \textit{ABCG2} variants (OR=2.7, p=3.0×10^{-5}) was similar to that of the common variants, Q126X (OR=3.4, p=3.2×10^{-16}) and Q141K (OR=2.3, p=2.7×10^{-16}).

\textbf{Conclusions} This study revealed that multiple common and rare variants of \textit{ABCG2} are independently associated with gout. These results could support both the ‘Common Disease, Common Variant’ and ‘Common Disease, Multiple Rare Variant’ hypotheses for the association between \textit{ABCG2} and gout susceptibility.

\textbf{INTRODUCTION}

Gout is the most common form of inflammatory arthritis and is caused by hyperuricaemia. Many previous studies have indicated that dysfunctional variants (rs72552713 (Q126X) and rs2231142 (Q141K)) of the gene encoding ATP-binding cassette transporter subfamily G member 2/breast cancer resistance protein (\textit{ABCG2}/\textit{BCRP}) increase the risk of gout/hyperuricaemia,\cite{1,2} and these variants increased the risk of gout benefiting an OR of more than 3.\cite{3,4} Thus, the effects of common \textit{ABCG2} variants on gout susceptibility are very strong, whereas any effect of rare \textit{ABCG2} variants is still unknown.

In this study, we first identified common and rare non-synonymous variants of \textit{ABCG2} by target exon sequencing of genomes from Japanese male patients with gout and healthy controls. Second, we evaluated the non-synonymous variants using three different protein prediction algorithms (Sorting Intolerant from Tolerant (SIFT) and PolyPhen-2). Stratified association analyses and multivariate logistic regression analysis were performed to evaluate the effects of rare and common \textit{ABCG2} variants on gout susceptibility.

\textbf{Key messages}

\begin{itemize}
  \item What is already known about this subject?
    - Common dysfunctional variants (Q126X and Q141K) of \textit{ABCG2} are risk factors for gout/hyperuricaemia, which supports the ‘Common Disease, Common Variant (CDCV)’ hypothesis.
  \item What does this study add?
    - Multiple common and rare variants of \textit{ABCG2} are independently associated with gout.
    - This study supports both the CDCV and ‘Common Disease, Multiple Rare Variant’ hypotheses for the association between \textit{ABCG2} and gout susceptibility.
  \item How might this impact on clinical practice?
    - These findings indicate that genotyping the rare variants of \textit{ABCG2} along with its common variants (Q126X and Q141K) is essential for evaluating the individual risk for gout.
\end{itemize}
prediction algorithms. Third, we performed molecular analyses of the urate transport function and evaluated the correlation between the functional analyses and the scores from the protein prediction algorithms. Finally, we performed association analyses between the ABCG2 variants and gout susceptibility.

METHODS

Patients and controls
This study was approved by the institutions’ Ethical Committees (National Defense Medical College, National Institute of Genetics and Nagoya University). All protocols were in accordance with the Declaration of Helsinki, and written informed consent was obtained from all participants. For the study, 480 Japanese males with gout were recruited from the Ryogoku East Gate Clinic (Tokyo, Japan). All patients were clinically diagnosed with primary gout according to the criteria established by the American College of Rheumatology. Patients with inherited metabolic disorders, including Lesch-Nyhan syndrome, were excluded from this study. As the control group, 480 healthy Japanese males without hyperuricaemia (serum uric acid (SUA) levels>7.0 mg/dL) or history of gout were recruited from the participants of the Shizuoka Study, which is a part of the Japan Multi-Institutional Collaborative Cohort Study (J-MICC Study). The mean age (±SD) of the case and control groups was 46.2 years (±9.8) and 52.3 years (±7.9), respectively, and their mean body mass index (±SD) was 25.3 kg/m² (±3.3) and 23.2 kg/m² (±2.6), respectively.

Targeted sequencing
Genomic DNA was extracted from the whole peripheral blood cells of the participants. We performed targeted exon sequencing of ABCG2 with a pool and capture method described in a previous study. Briefly, the extracted DNA was quantified using the Qubit dsDNA BR Assay Kit (Thermo Fisher Scientific, Waltham, Massachusetts, USA) on FilterMax F5 Multi-Mode Microplate Readers (Molecular Devices, Sunnyvale, California, USA). Twenty nanogram of DNA was simultaneously fragmented and ligated with adapters using the SureSelect QXT Library Prep Kit (Agilent Technologies, Santa Clara, California, USA). The 96 fragmented libraries with distinct indexed adapters were pooled in equimolar amounts. Target enrichment was then performed using the SeqCap EZ choice system (Roche Diagnostics, Tokyo, Japan). A DNA probe set complementary to the target region was designed using NimbleDesign (https://design.nimblegen.com). The libraries were sequenced on an Illumina HiSeq 2500 platform in rapid run mode with 2×150 bp paired-end modules (Illumina).

Variant calling and annotation
The generated sequences were aligned to a human reference genome (hg19) using BWA for removing the PCR duplicates. Local realignment and base quality recalibration were implemented using GATK. Genetic variations, including single nucleotide variants (SNVs) and short insertions and deletions (indels), were determined using HaplotypeCaller walker of GATK. Functional annotation of the identified variants was implemented using ANNOVAR.

Functional analysis
To estimate the functions of the ABCG2 variants, we used the protein prediction algorithms, Sorting Intolerant from Tolerant (SIFT) and Polymorphism Phenotyping v2 (PolyPhen-2). For PolyPhen-2, both PolyPhen-2 HumVar and PolyPhen-2 HumDiv were used. PolyPhen-2 HumVar is designed for distinguishing mutations with drastic effects from abundant mildly deleterious alleles, whereas PolyPhen-2 HumDiv is targeting rare alleles at loci potentially involved in complex phenotypes. To evaluate these protein algorithms, we performed functional analysis of ABCG2-mediated urate transport for previously identified variants (N208S, N299S, E311K, L447V, S486N and V516M) in our laboratories as well as reported variants whose vesicles were available (V12M, Q1141K, V127I, G268R, P269S, S414N, G462R, V508I and A634V). We analysed the correlation between the urate transport function and the scores from these protein prediction algorithms. In addition, we performed functional analysis of one frameshift deletion (F506SfsX4) and four nonsense variants (Q126X, E334X, R575X and C608X).

Functional assays were performed to determine the urate transport activity of each ABCG2 variant, as described in previous studies. Briefly, using site-directed mutagenesis, vectors expressing the different ABCG2 variants were generated from a myc-ABCG2 wild-type (WT)/pcDNA3.1(+) plasmid that was prepared in our previous study. Plasma membrane vesicles were isolated from human embryonic kidney-derived cells that were transiently transfected with the vectors expressing the ABCG2 variants using a standard method or with empty vector as a control using general lipofection methods. The isolated membrane vesicles were stored at −80°C until use. Expression of ABCG2 protein in the membrane vesicles was examined by immunoblotting with an anti-myc antibody (see online supplementary figure S1) according to our previous studies. Then, using a rapid filtration technique, the [3H]-urate transport assay was performed for the ABCG2-expressing or control membrane vesicles. Based on the radioactivity detected in the membrane vesicles, the urate transport activity was calculated based on the formula; incorporated clearance (μL/mg protein/min)=incorporated urate level (DPM/mg protein/min)/urate level in incubation mixture (DPM/μL). By subtracting the urate transport activity in the absence of ATP from that in the presence of ATP, ATP-dependent urate transport activity was also determined.
Statistical analysis

Statistical analyses were performed using SPSS v.22.0J (IBM Japan, Tokyo, Japan).

We selected missense and nonsense SNVs and indels in the exons of ABCG2 based on the DNA reference sequence NM_004827 for association analyses and excluded synonymous SNVs in ABCG2 exons as well as variants in introns or untranslated regions. Rare variants and common variants were defined when the minor allele frequencies (MAF) were <1% and ≥1%, respectively. MAF in the Japanese population was determined based on the Japanese in Tokyo (JPT) population from the 1000 Genomes Project data (http://www.internationalgenome.org/). We analysed multiple rare non-synonymous variants using the Collapsing method. If a rare allele was present at any of the variant sites, an individual was regarded as a rare variant carrier and as a non-carrier otherwise.

Since the effects of common dysfunctional variants of ABCG2, Q126X and Q141K, on gout susceptibility were very strong, we performed stratified association analyses between rare non-synonymous variants of ABCG2 and gout susceptibility by its common variants. The $\chi^2$ test was used for association analyses. Furthermore, multivariate logistic regression analysis was performed between the rare non-synonymous variants and the common variants (Q126X and Q141K) of ABCG2. The dominant model of the Collapsing method was applied for rare variants of ABCG2, whereas the additive codominant model was applied for the common variants.

RESULTS

Details of all the non-synonymous variants of ABCG2 found in the cases and the control samples by targeted exon sequencing are shown in Table 1. We identified 3 common and 19 rare non-synonymous variants of ABCG2. Genotype counts of the common non-synonymous variants (V12M, Q126X and Q141K) are shown in online supplementary table S1. For the identified rare variants, we observed 33 carriers among patients with gout and 19 rare non-synonymous variants of ABCG2 were found to be homozygous for rare variants.

Results of the functional analysis of 19 non-synonymous variants of ABCG2 are shown in figure 1A and table 2. The ATP-dependent urate transport activity was almost completely eliminated in several missense variants (S441N, G462R, F208S, G268R, S486N and V516M), nonsense variants (Q126X, R575X and E334X) and a frameshift deletion (F506SfsX4) of ABCG2 (figure 1A). In contrast, V12M and P269S variants did not show altered urate transport activity. The other rare variants addressed in this study exhibited lower transport activity as compared with WT. Based on the relationship between the protein level and urate transport activity of each ABCG2 variant (see online supplementary figures S1 and S2), the diminished function of each ABCG2 variant could primarily depend on the quantitative changes in the ABCG2 protein on the plasma membrane. On the other hand, several variants (L447V, N299S, S486N, V516M and S441N) would affect the intrinsic ability of ABCG2 as a urate transporter. Of note, the quantitative changes must have been due to the presence of each variant because the membrane vesicles were prepared by using certain procedure established in previous reports. In addition, previous reports showed that three variants (Q126X, S441N and F506SfsX4) disrupt the transport activity of ABCG2, whereas other three variants (V12M, A149P and P269S) have little effect on the transport activity.

The scores from SIFT were significantly correlated with the urate transport function (figure 1B; r=0.57, p=0.026). On the other hand, the scores of PolyPhen-2 were not significantly correlated; these scores tended to decrease as the urate transport function increased (figure 1C,D; r=-0.42, p=0.12 in PolyPhen-2 HumVar; r=-0.46, p=0.089 in PolyPhen-2 HumDiv). These correlations suggested that the protein prediction algorithms were useful for predicting changes in the transport function of ABCG2; however, some variants of ABCG2 showed inconsistent scores (table 2; P269S and S441N). Therefore, we determined the effects of ABCG2 variants using the following protocol: (1) when functional data were available, we used the results of urate transport analysis and (2) when functional data were not available, we used the scores from SIFT and PolyPhen-2. V12M and P269S variants were excluded from these analyses because they did not significantly decrease urate transport activity. The V12M variant did not show a significant association with gout susceptibility in the multivariate logistic regression analysis with the other common variants, Q126X and Q141K (table 3). In addition, the A149P variant was also excluded because it was not likely to cause functional changes, according to the scores of SIFT (1), PolyPhen-2 HumVar (0) and PolyPhen-2 HumDiv (0) (see online supplementary table S2). It was shown in a previous study through functional analysis that the A149P variant did not significantly affect the drug transport activity of ABCG2.

To evaluate the effects of rare variants by removing the effects of the common variants, stratified association analyses were performed, as shown in table 4. When the gout susceptibility was analysed for samples without Q126X or Q141K, rare non-synonymous variants of ABCG2 were found to increase the gout risk conferring OR to 3.2 (p=6.4×10⁻³, table 4). In the multivariate logistic regression analysis as well, rare non-synonymous variants of ABCG2 were found to be associated with gout susceptibility independent of the Q126X and Q141K variants (table 5). In addition, the effect size of rare variants of ABCG2 (OR=2.7, 95% CI 1.4 to 5.2, p=3.0×10⁻⁵) was similar to that of common variants Q126X (OR=3.4, 95% CI 2.0 to 5.6, p=3.1×10⁻⁶) and Q141K (OR=2.3, 95% CI 1.9 to 2.9, p=2.7×10⁻⁶⁵) (table 5). Thus, our findings indicated that multiple common and rare variants of ABCG2 are strongly and independently associated with gout susceptibility.
Common dysfunctional variants (Q126X and Q141K) of ABCG2, a urate transporter gene, have been shown to be strongly associated with gout susceptibility and age of onset of gout. Q126X, a common variant in the Japanese population, is a rare variant in Caucasian and African-American populations, whereas Q141K is a common variant in all these populations. The MAF of Q126X and Q141K are 0.024 and 0.322, respectively in the Japanese population (JPT from the 1000 Genomes Project).

ABCG2 excretes urate from the intestine and kidney, and its dysfunction causes ‘extrarenal urate underexcretion type’ and/or ‘renal urate underexcretion type’ gout. ABCG2-mediated intestinal urate excretion was also discovered in humans recently after investigation of haemodialysis and acute gastroenteritis patients. It was also shown that increased SUA could be a useful marker of intestinal impairment, because increased SUA of gastroenteritis patients was explained both by dehydration and by impaired intestinal epithelium which excretes urate via ABCG2. In addition, ABCG2 variants have been shown to have stronger effects on the risk of hyperuricaemia than major environmental risk factors such as obesity and heavy drinking.

In recent genome-wide association studies (GWASs) of clinically defined gout, the ABCG2 locus showed the most significant association with gout susceptibility. The ABCG2 locus was also the most significantly detected locus in GWASs of gout in Caucasian populations. These findings indicate that common variants of ABCG2 are extremely important in gout pathogenesis.

In addition to Q126X and Q141K, V12M is another common non-synonymous variant of ABCG2. A

haplotype frequency analysis in a previous study showed that the minor alleles of V12M, Q126X and Q141K were not simultaneously present in one haplotype. In other words, these three variants are in complete linkage disequilibrium. Therefore, the minor allele of V12M seems to have a protective effect on gout susceptibility, although it does not have an actual effect. In this study, we performed both univariate and multivariate logistic regression analyses of gout susceptibility in common variants of ABCG2 (V12M, Q126X and Q141K). Indeed,
V12M showed a significant association with gout susceptibility only in the univariate logistic regression analysis (see online supplementary table S3), although it was no more statistically significant after adjustment for Q126X and Q141K genotypes in the multivariate logistic regression analysis (p=0.27, table 3). This finding was also consistent with the results of the molecular functional analysis, in which the V12M variant did not show decreased urate transport (figure 1A). These findings showed that V12M had no significant protective effects against gout susceptibility, as shown in table 3.

Molecular functional analysis of transporters is useful for in vitro quantitative assessment of functional changes caused by non-synonymous variants and for evaluating the scores from the protein prediction algorithms. While functional analysis of the ABC transporters by a vesicle system is powerful, it takes considerable effort to analyse all the rare variants identified by targeted exon sequencing. Therefore, in this study, we performed functional analyses for half of the non-synonymous variants whose vesicles were available detected through the targeted exon sequencing (n=11, table 2) and previously identified rare variants (n=9, table 2). We then compared the results of the functional analyses with the scores from SIFT and PolyPhen-2. Based on these results, we predicted the functional changes of other missense variants (n=9) (see online supplementary table S2) with the protein prediction algorithms. We considered that it was reasonable to use molecular functional analyses and protein prediction algorithms in combination. We propose this as a suitable model for analysing rare variants of transporter genes to evaluate individual genetic risks for common diseases including gout.

Each variant was adjusted by the other two variants in this analysis. ABCG2, ATP-binding cassette transporter subfamily G member 2.

Previous studies have indicated that common variants of ABCG2 are risk factors for gout/hyperuricaemia. These studies supported the ‘Common Disease, Common Variant (CDCV)’ hypothesis, which states that common genetic variants are the major contributors to genetic susceptibility to common diseases. In contrast, recent genetic studies have suggested that multiple rare variants also play important roles in several
studies as well as this study have also supported the hypothesis for \textit{ABCG2} susceptibility. Results of this study support the CDMRV of both common and rare variants of \textit{ABCG2} on gout susceptibility. In addition, we used logistic regression analysis to evaluate the effect of both common and rare variants of \textit{ABCG2} on gout susceptibility. Results of this study support the CDMRV hypothesis for \textit{ABCG2} and gout, whereas many previous studies have also supported the CDCV hypothesis. In this study, gene-based stratified association analyses revealed an association between rare non-synonymous variants of \textit{ABCG2} and gout susceptibility. In addition, we used logistic regression analysis to evaluate the effect of both common and rare variants of \textit{ABCG2} on gout susceptibility. Results of this study support the CDMRV hypothesis for \textit{ABCG2} and gout, whereas many previous studies have also supported the CDCV hypothesis. We found that multiple rare variants as well as common variants of \textit{ABCG2} are independently associated with gout risk. These results further indicate that \textit{ABCG2} is a key molecule in the pathogenesis of gout. Evaluating the risk associated with common and rare variants of individual genes could help in developing precision medicine or personalised genome medicine for common diseases such as gout. Our results showed that genotyping the rare variants of \textit{ABCG2} along with its common variants (Q126X and Q141K) is essential for evaluating the individual risk for gout. Although the rare variants of \textit{ABCG2} showed highly significant association with gout susceptibility in this study, the number of the participants is small compared with other association analyses of rare genetic variants. Further studies are required in order to find other important rare variants of \textit{ABCG2} and perform more detailed analyses.

In summary, our findings revealed that multiple common and rare variants of \textit{ABCG2} could cause gout. Thus, this study could support both ‘CDCV’ and ‘CDMRV’ hypotheses, and we proposed the novel ‘Common Disease, Multiple Common and Rare Variant’ model for the association between \textit{ABCG2} and gout.

Only non-synonymous SNVs or indels with minor allele frequency less than 1% were considered rare non-synonymous variants in this analysis. Since the P268S variant of \textit{ABCG2} did not decrease urate transport activity, it was excluded from this analysis. The A149P variant of \textit{ABCG2} was also excluded from this analysis due to its scores of SIFT and PolyPhen-2 as well as a previous report of functional analysis. Each variant was adjusted by the other two variants in this analysis. Since the P268S variant of \textit{ABCG2} did not decrease urate transport activity, it was excluded from this analysis. The A149P variant of \textit{ABCG2} was also excluded from this analysis due to its scores of SIFT and PolyPhen-2 as well as a previous report of functional analysis.

Acknowledgements

We thank all the participants for their generous involvement in this study. We also thank members of the Japan Multi-Institutional Collaborative Cohort Study (J-MICC Study) Shizuoka Field for supporting the study. We are indebted to J. Kajiwara, J. Kitayama, S. Miyase, M. Takahashi and T. Chiiba for genetic analysis. We are also indebted to A. Tomukusa, K. Oyama, M. Naito, A. Hishida, N. Hamajima and H. Tanaka for sample collection. We also thank T. Shimizu and A. Toyoda for helpful discussions.

Contributor

Thigahime, TT, HNakaoka and YToyoda contributed equally.

Contributors

TH, TT, HNakaoka, KH, NS and HMa conceived and designed this study. BS and KY assisted with research design. KW, RD and H0 collected samples and analysed clinical data. TH, HNakaoka, SS, SS, MK, AN, AA, Yt da, YK, KI, KH, NS and HMs performed genetic analysis. TT, YTo, HM and YI performed functional analysis. TH, HNakaoka, HNaka, TN and HMa performed statistical analyses. BS, KY, KH, Tho, KI, HS, TRM and NS provided intellectual input and assisted with the preparation of the manuscript. TH, TT, HNakaoka, YTo and HMa wrote the manuscript. All authors have read and approved the final version of the manuscript.

Funding

This study was supported by grants from the Ministry of Education, Culture, Sports, Science and Technology (MEXT) of Japan, including MEXT KAKENHI (Nos 25293145 and 15K15227), Grants-in-Aid for Scientific Research on Priority Areas (No 17015018) and Innovative Areas (Nos 22150001 and 22150002) and JSPS KAKENHI Grants (Nos 16H06277 and 16H06279), the Ministry of Health, Labour and Welfare of Japan, the Ministry of Defense of Japan, the Japan Society for the Promotion of Science, the Kawano Masanori Memorial Foundation for Promotion of Pediatrics, the Gout Research Foundation of Japan and the Health Research Council of NZ.

Competing interests

TT, TN, KI, HS, NS and HMs have a patent pending based on the work reported in this paper.

Patient consent

Obtained.

Provenance and peer review

Not commissioned; externally peer reviewed.

Data sharing statement

No additional data are available.
