ABSTRACT

Objective: To evaluate effects of the anti-interleukin-6 receptor monoclonal antibody sarilumab administered with conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) on patient-reported outcomes (PROs) in the TARGET trial in patients with rheumatoid arthritis (RA) with inadequate response or intolerance to tumour necrosis factor inhibitors (TNF-IR).

Methods: 546 patients (81.9% female, mean age 52.9 years) were randomised to placebo, sarilumab 150 or 200 mg subcutaneously every 2 weeks + csDMARDs. PROs included patient global assessment (PtGA); pain and morning stiffness visual analogue scales; Health Assessment Questionnaire Disability Index (HAQ-DI); Short Form-36 Health Survey (SF-36); FACIT-Fatigue (FACIT-F); Work Productivity Survey-Rheumatoid Arthritis (WPS-RA) and Rheumatoid Arthritis Impact of Disease (RAID). Changes from baseline at weeks 12 and 24 were analysed using a mixed model for repeated measures; post hoc analyses included percentages of patients reporting improvements $\geq$ minimum clinically important differences (MCID) and scores $\geq$ normative values.

Results: Sarilumab + csDMARDs doses resulted in improvements from baseline at week 12 vs placebo + csDMARDs in PtGA, pain, HAQ-DI, SF-36 and FACIT-F that were maintained at week 24. Sarilumab improved morning stiffness and reduced the impact of RA on work, family, social/leisure activities participation (WPS-RA) and on patients' lives (RAID). Percentages of patients reporting improvements $\geq$ MCID and $\geq$ normative scores were greater with sarilumab than placebo.

Conclusions: In patients with TNF-IR RA, 150 and 200 mg sarilumab + csDMARDs resulted in clinically meaningful patient-reported benefits on pain, fatigue, function, participation and health status at 12 and 24 weeks that exceeded placebo + csDMARDs, and were consistent with the clinical profile previously reported.

Trial registration number: NCT01709578; Results.

Key messages

What is already known about this subject?

- While sarilumab has demonstrated significant improvement in symptomatic, functional and radiographic outcomes in rheumatoid arthritis (RA) clinical trials, assessing patient-reported outcomes (PROs) is an important consideration when making treatment decisions.

What does this study add?

- This analysis shows that treatment with sarilumab with conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs) resulted in statistically or nominally significant improvements in PROs in patients with an inadequate response or intolerance to tumour necrosis factor- α inhibitors (TNF-IR) in moderate-to-severely active RA.
- Patients reported benefits of sarilumab on specific domains of importance, including pain, fatigue, morning stiffness, physical function, participation and reduced impact of disease on their general health status: the percentages reporting improvements $\geq$ minimum clinically important differences and that met or exceeded normative values were greater with sarilumab than placebo.

How might this impact on clinical practice?

- In addition to clinical responses, sarilumab provides meaningful, important benefits in outcomes of importance to patients.

INTRODUCTION

Patient-reported outcomes (PROs) are important endpoints that supplement physician-reported and laboratory measures when evaluating treatment responses in

rheumatoid arthritis (RA).^{1–3} Clinical measures of RA such as the American College of Rheumatology (ACR) response criteria incorporate PROs that capture pain, physical function and global assessment of disease.⁴ However, PROs that assess fatigue, health-related quality of life (HRQOL) or health status and effects of RA on work within and outside the home and family, social and leisure activities are not routinely part of assessment of disease activity, but are important since these outcomes have profound effects on patients' daily lives.^{5–8}

Sarilumab is a human immunoglobulin (IgG1) anti-interleukin-6 receptor α (anti-IL-6R α) monoclonal antibody that selectively binds to membrane-bound and soluble IL-6R α , inhibiting IL-6-mediated signal transduction;⁹ IL-6 contributes to inflammation and joint destruction¹⁰ and mediates pain and fatigue in RA.^{11–12} Sarilumab was evaluated in two phase III, randomised, placebo-controlled trials (RCTs), MOBILITY and TARGET. Consistent with international consensus and guidelines,^{1–4} and the importance of the patient perspective, PROs were assessed in both pivotal sarilumab trials. The MOBILITY RCT,¹³ which evaluated sarilumab in combination with methotrexate (MTX) in moderate-to-severe patients with RA with inadequate responses to MTX, demonstrated benefits across multiple PROs, including patient global assessment of disease activity (PtGA), pain, physical function, fatigue and general health status compared with placebo. The TARGET trial evaluated sarilumab in combination with conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) in patients with moderate-to-severe RA with inadequate responses or intolerance to tumour necrosis factor inhibitors (TNF-IR). Subcutaneous administration of sarilumab 200 and 150 mg every 2 weeks (q2w) demonstrated significant improvement in symptomatic and functional outcomes, with a safety profile consistent with IL-6 blockade.¹⁴ This paper reports the effects of sarilumab treatment on the PROs included in the TARGET RCT.

METHODS

Study design and population

Details of the TARGET multicentre RCT have been previously described;¹⁴ briefly, patients with TNF-IR RA received subcutaneous placebo or sarilumab 150 or 200 mg q2w + csDMARDs for 24 weeks. At week 12 and onwards, patients with <20% improvement from baseline in swollen or tender joint counts for at least two consecutive assessments separated by ≥ 4 weeks were offered rescue with open-label sarilumab 200 mg q2w. The first patient was enrolled in October 2012, and the last completed the trial in March 2015. This RCT received approval from the Institutional Review Board/Independent Ethics Committee of the investigational centres and was performed in accordance with the Declaration of Helsinki; all patients provided written, informed consent prior to participation (ClinicalTrials.gov, NCT01709578).

Inclusion criteria included: age ≥ 18 years; diagnosis of RA by ACR/The European League Against Rheumatism (EULAR) 2010 classification criteria;¹⁵ moderate-to-severely active disease; disease duration ≥ 6 months; inadequate responses or intolerance to ≥ 1 TNFi and continuous treatment with standard dose(s) of ≥ 1 csDMARDs (combination MTX + leflunomide was not allowed) for ≥ 12 weeks before baseline and stable doses ≥ 6 weeks before screening. Patients were excluded if they had uncontrolled concomitant diseases, significant extra-articular manifestations of RA, functional class IV RA, other inflammatory diseases, current/recurrent infections or were receiving prednisone (or equivalent) > 10 mg/day.

Patient-reported outcomes

All PROs were translated into the appropriate languages, and included PtGA and pain, both evaluated using a 0–100 mm visual analogue scale (VAS) and Health Assessment Questionnaire Disability Index (HAQ-DI), all of which were assessed as part of the ACR response criteria.⁴ The Medical Outcomes SF-36 Health Survey V.2 (SF-36)¹⁶ assesses eight domains (physical functioning (PF), role physical (RP), bodily pain (BP), general health perceptions (GH), vitality (VT), social functioning (SF), role emotional (RE) and mental health (MH)) on a scale of 0–100 with higher scores indicating better health status, combined into physical (PCS) and mental (MCS) component summary scores with normative values of 50 and SDs of 10.

Other PROs included Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F),¹⁷ Work Productivity Survey-Rheumatoid Arthritis (WPS-RA),¹⁸ Rheumatoid Arthritis Impact of Disease (RAID)¹⁹ and morning stiffness using a 0–100 mm VAS.²⁰ The WPS-RA consists of nine items, assessing employment status, productivity with regard to absenteeism (days missed), presenteeism (days with work productivity reduced by $\geq 50\%$) and rate of RA interference in work within and outside the home (0 = no interference to 10 = complete interference), as well as participation measured as days missed in family, leisure and social activities, all with a 1-month recall period. The RAID is a composite measure based on seven domains (pain, functional disability, fatigue, physical and emotional well-being, quality of sleep and coping) scored on 0–10 numerical rating scales (NRS); weighted by patient assessment of relative importance, with higher scores indicating greater impact of RA.

PtGA, pain and HAQ-DI were evaluated at baseline and weeks 2, 4, 8, 12, 16 and 24. Change from baseline in HAQ-DI at week 12 was a coprimary endpoint. SF-36 and WPS-RA were assessed at baseline and weeks 4, 12 and 24. FACIT-F, RAID and morning stiffness were assessed at baseline and weeks 2, 4, 12 and 24.

Statistical analyses

Analyses were based on the intent-to-treat (ITT) population, which included all randomised patients. A mixed

model for repeated measures (MMRM) tested least square mean (LSM) changes from baseline between each active treatment group and placebo at weeks 12 and 24. The MMRM included treatment, region, number of previous TNFi, visit and treatment-by-visit interaction as fixed effects and baseline PRO scores as covariates. Data collected after treatment discontinuation or rescue were set to missing. Statistical significance was claimed for those outcomes above the break in the predefined hierarchy; otherwise, *p* values are considered nominal. As the WPS-RA consists of independent items, O'Brien's global test was first used to determine overall significance at week 24 prior to further evaluation.²¹

Responder analyses evaluated the proportion of patients who reported improvements meeting or exceeding minimum clinically important differences (MCID) for each PRO.^{22–23} These were prespecified for HAQ-DI using MCID values ≥ 0.22 ²² and ≥ 0.3 ,^{24–25} and conducted post hoc for other endpoints based on 10 points for PtGA,²⁶ pain and morning stiffness VAS scales;^{23–27} 2.5 points for SF-36 PCS and MCS, and 5 points for individual domains;²⁸ 4 points in FACIT-F¹⁷ and 3 points for RAID.²⁹ Patients who discontinued treatment (placebo, *n*=17; sarilumab 150 mg, *n*=31; sarilumab 200 mg, *n*=25) or used rescue medication (placebo, *n*=63; sarilumab 150 mg, *n*=25; sarilumab 200 mg, *n*=26) were considered non-responders, and differences in proportions between treatments were evaluated using a two-sided Cochran-Mantel-Haenszel test (stratified by number of previous anti-TNFs and region). Estimates of the number-needed-to-treat (NNT), ie, the number of patients who must be treated to obtain the outcome of interest in one patient, were calculated as the reciprocal of the differences in responder rates between sarilumab and placebo for patients who reported improvements $\geq$ MCID at week 24.³⁰ In addition to the overall population, the percentage of PRO responders in the subpopulation of ACR20 responders was determined post hoc. Other post hoc analyses included the proportion of patients who reported normative values in FACIT-F and SF-36 PCS, MCS and domain scores at week 24.

Post hoc correlation analysis (Pearson *r*) explored potential relationships between reported individual PRO scores at week 24 and clinical measures of disease activity (28-joint Disease Activity Score using C reactive protein (DAS28-CRP) and Clinical Disease Activity Index (CDAI)).

All analyses were performed using SAS V.9.2 (SAS Institute, Cary, SC).

RESULTS

Demographic and disease characteristics

Baseline demographic and disease characteristics were balanced across treatment groups (table 1). Patients were predominantly female (81.9%), with a mean duration of RA since diagnosis of 12.1 years and all were

patients with TNF-IR. Most patients (92.3%) had failed their previous agent due to inadequate responses, of these, 42% were recorded as having a primary failure to the prior TNF, and 58% as having secondary failures. A total of 20.6–25.4% across treatment groups of the total population had received >1 prior TNFi.

Baseline PRO scores were balanced across treatment groups (table 1), and indicative of substantial disease-associated impairment. At baseline, 33.1%, 33.7% and 35.7% of patients in placebo, sarilumab 150 and 200 mg groups, respectively, reported they were currently employed outside of the home based on the WPS-RA. Baseline values for the individual WPS-RA items indicated a substantial impact of RA on productivity within and outside the home, and >5 days missed participating in family, social and leisure activities during the past month (table 1).

Changes from baseline

There were no treatment-by-visit interactions. LSM changes from baseline at week 12 in PtGA and pain were greater with sarilumab 150 and 200 mg than placebo (both $p<0.0001$), and at week 24 (150 mg; $p<0.001$; 200 mg; $p<0.0001$; table 2). Compared with placebo, statistically significant improvements in change from baseline in HAQ-DI were reported with both doses of sarilumab at weeks 12 ($p<0.001$) and 24 ($p<0.05$), and SF-36 PCS at week 24 ($p<0.001$). Greater improvements reported with both sarilumab doses versus placebo at week 12 in FACIT-F, morning stiffness, SF-36 PCS and MCS and RAID ($p<0.05$) were maintained at week 24 with the exception of SF-36 MCS (table 2). Improvements in PtGA, pain, HAQ-DI and FACIT-F scores were reported at 2 weeks after start of treatment (see online supplementary figure S1).

As shown in figure 1, baseline scores indicated substantial decrements across all SF-36 domains relative to US normative values for an age-matched and gender-matched population, as a benchmark comparison. Improvements were reported across all SF-36 domains at weeks 12 and 24, and were greater with sarilumab ($p<0.05$) with the exceptions of GH, RE and MH with 150 mg at weeks 12 and 24 and RE with 200 mg at week 24 (table 2 and figure 1). Mean week 24 scores in the 200 mg sarilumab group approached normative values for the VT domain (figure 1).

Global testing indicated that sarilumab treatment resulted in greater overall improvement in the WPS-RA compared with placebo at week 24 ($p=0.0004$ and $p=0.0003$ for 150 and 200 mg dose groups, respectively). Among those employed outside the home, patients reported reduced lost productivity due to presenteeism (ie, days with work productivity reduced by $\geq 50\%$) with the largest benefit on absenteeism (days missed), with the 200 mg dose versus placebo (-3.2 vs -2.0 ; $p<0.05$). Patients receiving sarilumab 200 mg also reported greater reductions in the rate of RA interference with work productivity (-2.7 vs -1.6 ; $p<0.05$; figure 2A). Both

Figure 1 Spidergram of mean SF-36 domain scores at baseline and weeks 12 (A) and 24 (B) for sarilumab 150 mg and 200 mg+csDMARDs compared with placebo+csDMARDs relative to age- and gender-matched general population norms. All scores on a scale of 0 to 100 (0=worst, 100=best). For week 12, n=181 for placebo, n=165 for sarilumab 150 mg and n=184 for sarilumab 200 mg; for week 24, n=99 for placebo, n=126 for sarilumab 150 mg and n=135 for sarilumab 200 mg. BP, Bodily Pain; GH, General Health Perceptions; MH, Mental Health; NS, not significant; PF, Physical Functioning; RE, Role Emotional; RP, Role Physical; SF, Social Functioning; VT, Vitality.

sarilumab doses resulted in greater reductions versus placebo in work days within the home missed ($p<0.001$), days with outside help required ($p<0.05$) and the rate of RA interference with household work ($p<0.001$; figure 3B). The number of days missed of family, social or leisure activities was reduced from baseline by 2.0 days with placebo compared with greater reductions with sarilumab: 3.5 days with 150 mg ($p<0.05$) and 4.1 days ($p<0.001$) with 200 mg (figure 2C).

Responder analyses

In prespecified analysis of HAQ-DI and post hoc analyses of other PROs, percentages of patients who reported improvements $\geq$ MCID (ie, the proportion of responders) were higher with both doses of sarilumab versus placebo across all PROs ($p<0.05$; figure 3A). Additionally, more patients receiving sarilumab reported values $\geq$ MCID in individual SF-36 domains with exception of GH for the 150 mg dose and RE for both doses (figure 3B). These resulted in NNTs ranging from 3.8 (sarilumab 200 mg for pain) to 12.2 (sarilumab 150 mg for RE; figure 3). In the subgroup of ACR20 responders (n=274; 50.2% of the total population), the majority of patients reported improvements $\geq$ MCID across PROs (range, 52.5–98.2%; data not shown).

The percentages of patients who reported normative values at baseline in FACIT-F and SF-36 domains ranged from $<1\%$ for BP to 22.1% for VT (see online supplementary figure S2A). At week 24 (see online supplementary figure S2B), the percentages of patients

reporting scores $\geq$ normative values across FACIT-F and individual SF-36 domains increased with both doses of sarilumab (ranging from 14.9% for RP to 50.5% for VT) with greater increases compared with placebo ($p<0.05$ for both sarilumab doses for PF and 200 mg for BP).

Correlation analyses

There were moderate correlations between individual PROs and clinical measures of disease activity (DAS28-CRP and CDAI) at week 24, with the exception of strong correlations between pain, PtGA and the BP domain of SF-36 with DAS28-CRP, and low correlations between SF-36 domains GH with CDAI and MH with DAS28-CRP and CDAI (figure 4). The majority of correlations between individual PROs and SF-36 domains were moderate; the strongest were between those that measure similar constructs: FACIT-F with VT ($r=0.79$), HAQ-DI with PF ($r=-0.75$) and VAS pain with BP ($r=-0.76$). There was also a strong correlation between PtGA and pain VAS ($r=0.87$).

DISCUSSION

In addition to clinical data, a patient's perception of their disease impact is an important consideration when making treatment decisions. These analyses from the TARGET RCT complements the clinical efficacy and safety data previously reported,¹⁴ and demonstrates that treatment with sarilumab + csDMARDs resulted in patient-reported benefits that were clinically meaningful

Figure 2 Change from baseline at week 24 in Work Productivity Survey-Rheumatoid Arthritis; recall period is the past month. (A) Work outside of the home. (B) Household work. (C) Days missed of family, social, leisure activities. Scale for rate of interference is 0=no interference to 10=complete interference; all other scales represent days. * $p < 0.05$ vs placebo; † $p < 0.0001$ vs placebo; ‡ $p < 0.001$ vs placebo. csDMARDs, conventional synthetic disease-modifying anti-rheumatic drugs.

in pain, fatigue, function, participation and health status. In TARGET, consistently greater improvements were reported by patients who received sarilumab compared with those who received placebo, with dose-dependent benefits favouring 200 mg; favourable results observed at week 12 were maintained at week 24. These results are similar to patient-reported benefits in MOBILITY¹³ which evaluated sarilumab plus MTX in patients with MTX-IR. Notably, reported improvements at week 24 in TARGET were comparable to those in MOBILITY for those PROs evaluated in both RCTs, despite higher baseline disease activity among patients with TNF-IR enrolled in TARGET.

Fatigue, which along with pain may be mediated by IL-6, the target of sarilumab,^{11 12} remains a persistent problem³¹ and is reported to be of greater concern to patients than tender and swollen joints.^{7 32} Improvements in fatigue were reported in TARGET based on FACIT-F, supported by changes in the conceptually similar SF-36 VT domain as well as one of the domains of RAID, a disease-specific composite measure

that assesses the impact of RA on domains of greatest importance to patients. RAID was not included in MOBILITY, and indeed, has not been used in many previous RA RCTs. Its inclusion in TARGET provided further support for the broad benefits of sarilumab improving the lives of patients with RA.

Another disease-specific measure included in TARGET was the WPS-RA, which demonstrated that RA interference with work within and outside the home was reduced with sarilumab, recognising that the proportion of patients working outside the home was low. Patients additionally reported reductions in the number of days missed of family, social or leisure activities. Such an impact on work within the home as well as participation in other activities has infrequently been captured in RA clinical trials. These observations indicate that in addition to the improvements in physical function reported by other measures (eg, HAQ-DI and SF-36 PF and RP domains), there are also direct patient-reported benefits in the ability to participate in work, family and social/leisure activities.

Figure 3 Post hoc analysis of differences from placebo in the percentage of patients reporting improvements $\geq$ MCID at week 24. (A) Patient global assessment (PtGA), Pain visual analogue scale, FACIT-Fatigue (FACIT-F), Health Assessment Questionnaire-Disability Index (HAQ-DI), SF-36 physical and mental component scores (PCS and MCS), morning stiffness visual analogue scale and Rheumatoid Arthritis Impact of Disease (RAID). (B) SF-36 individual domains. * $p < 0.05$ for the response rate relative to placebo. † $p < 0.0001$ for the response rate relative to placebo. ‡ $p < 0.001$ for the response rate relative to placebo. BP, Bodily Pain; csDMARDs, conventional synthetic disease-modifying anti-rheumatic drugs; GH, General Health perceptions; MH, Mental Health; NNT, number needed to treat; PF, Physical Functioning; RE, Role Emotional; RP, Role Physical; SF, Social Functioning; VT, Vitality.

Post hoc analyses consistently indicated that a higher proportion of patients reported improvements $\geq$ MCID with sarilumab compared with placebo ($p < 0.05$), indicating that mean changes from baseline translated into clinically meaningful benefits on an individual patient level. Estimates of NNTs indicated that, with few exceptions, between four and nine patients would need to be treated to achieve these levels of benefit. Additionally, the proportion of patients who reported normative values in SF-36 and FACIT was higher with sarilumab than placebo. Normative values represent a level of response commensurate with individuals without arthritis or other chronic conditions, previously not expected in RA RCTs.

Consistent with prior research,^{13 26} strong correlations were observed for conceptually related domains, including FACIT-F with SF-36 VT, HAQ-DI with SF-36 PF and SF-36 BP with pain VAS. Strong correlations were evident for patient global scores with pain VAS and

FACIT-F at week 24, supporting the importance of pain and fatigue to patients' overall perception of their disease activity.³³ Moderate correlations were evident between other PROs, and between most PROs and clinical measures of disease activity (DAS28-CRP and CDAI), supporting the concept that multiple PROs reflect different domains of response from clinical measures and from each other. These findings indicate the importance of a full range of PRO measures to comprehensively assess treatment benefit.

Strengths and limitations

A main strength of this trial was the use of PROs covering a wide range of symptoms and impact of RA, including disease-specific and generic measures to comprehensively evaluate patients' perspectives and to place them in the context of the general population. Another is inclusion of the WPS-RA, which captures household work productivity as well as participation in

family/social and leisure activities that are overlooked in other productivity measures. A limitation of WPS-RA may be that it underestimates presenteeism,³⁴ since it only assesses days with $\geq 50\%$ lost productivity. Further, the use of hierarchical testing procedures limited the ability to interpret some of the PRO data with regard to claims of statistical significance. One limitation of the analysis of the proportion of patients reporting scores $\geq$ normative values is that we used US population norms. Normative data for SF-36 are not available for all countries, but for those that are available are generally close to US norms. As a benchmark comparison, US norms should give a reasonable idea of the proportion of patients reporting values in the range that would be expected in the general population.

In conclusion, the multicentre TARGET RCT demonstrated patient-reported benefits with sarilumab across a range of PROs that were consistent with those in the MOBILITY trial, but in a more difficult-to-treat population. These findings demonstrate that targeting IL-6 with sarilumab represents an appropriate and effective management strategy in these patients.
