Autoantibodies against specific post-translationally modified proteins are present in patients with lupus and associate with major neuropsychiatric manifestations

Rory C Monahan, Michelle D van den Beukel, Nicole V Borggreven, Rolf Fronczek, Tom W J Huizinga, Margreet Kloppenburg, Leendert A Trouw

ABSTRACT

Background Although autoantibodies are an important hallmark of systemic lupus erythematosus (SLE), most are not specific for SLE or any of its clinical manifestations. Autoantibodies against post-translationally modified (PTM) proteins have been studied extensively in rheumatoid arthritis and associate with disease progression. While PTMs have also been detected in patients with SLE, studies on anti-PTM antibodies remain scarce. We studied the presence of anti-PTM antibodies in SLE and neuropsychiatric SLE (NPSLE), a manifestation that lacks serological markers.

Methods IgG antibody responses against six PTMs (malondialdehyde–acetaldehyde adducts (MAA), advanced glycation end-products (AGE), carbamylation (CarP), citrullination, acetylation and nitration) were tested using ELISA in sera of 349 patients with SLE (mean age 44±13 years; 87% female) and compared with 108 healthy controls. Levels and positivity were correlated with clinical features and SLE manifestations.

Results Anti-MAA, anti-AGE and anti-CarP antibodies were more prevalent in SLE compared with controls (MAA: 29% vs 3%, AGE: 18% vs 4%, CarP: 14% vs 5%, all p<0.0001). Anti-MAA and anti-AGE antibodies correlated with clinical manifestations and serological inflammatory markers. Patients with major NPSLE showed higher positivity of anti-MAA (39% vs 24%, p=0.01) and anti-CarP antibodies (20% vs 11%, p=0.04) than patients without major NPSLE. In addition, anti-PTM antibody levels correlated with brain volumes, an objective measure of nervous system involvement.

Conclusions In our NPSLE cohort, a subset of patients with SLE have anti-PTM antibodies against MAA, AGE and CarP modified proteins. Interestingly, anti-MAA and anti-CarP were more prevalent in NPSLE, a manifestation for which no biomarkers exist.

INTRODUCTION

Systemic lupus erythematosus (SLE) is a heterogeneous autoimmune disease characterised by a global loss of self-tolerance. Although autoantibodies are an important hallmark of SLE, many autoantibodies are not specific for SLE or specific SLE manifestations, such as neuropsychiatric involvement (NPSLE).

Many different types of biomarkers exist and may be used in different contexts for diagnostic, prognostic and predictive purposes. In rheumatoid arthritis (RA), the identification of anti-citrullinated protein antibodies (ACPAs), antibodies (Abs) directed against a post-translational modification (PTM), has facilitated the diagnostic process and created new insights in its pathophysiology. Note-worthy, the presence of specific anti-PTM Abs also facilitates discrimination between
phenotypes within RA, as they associate with more severe RA. It is possible that Abs against PTMs may also contribute to the identification of specific phenotypes in patients with SLE.

PTMs can occur naturally, as part of physiological functions, or may be the result of enzymatic or chemical processes. SLE has been associated with a dysregulated metabolic state and elevated levels of reactive oxygen species, which enhances the formation of PTMs. In some situations, immune responses against PTMs can develop, leading to anti-PTM Abs. To date, anti-PTM Ab studies in SLE have mainly focused on ACPA and anti-carbamylated protein (anti-CarP) Abs, which associated with increased joint damage. Several anti-PTM Abs have been associated with general disease activity (SLE Disease Activity Index (SLEDAI)) in lupus. In addition, phospholipid β2-glycoprotein-I is reported to be modified by PTMs making it more antigenic. Around 35% of all patients with SLE are positive for Abs against these phospholipids, which are associated with antiphospholipid syndrome. Overall, studies on anti-PTM Abs in patients with SLE remain limited and techniques to measure anti-PTM Abs vary greatly.

Based on previous studies, we hypothesised that SLE activity can lead to the generation of PTMs on relevant antigens and that there is specificity in breaking tolerance towards these neoantigens. In this study, we focused on IgG antibodies against six different PTMs, selected based on their association with activity in other diseases and variation in location in the protein, configuration and reversibility. We aimed to first study the presence of these six anti-PTM Abs in patients with SLE using a standardised method to assess specific anti-PTM Ab reactivities. Second, we aimed to assess the association between anti-PTM Abs and clinical phenotypes of SLE, in particular NPSLE, for which virtually no biomarkers exist. Additionally, both the subjective clinical diagnosis of NPSLE and objective evidence of nervous system involvement, namely radiological measurements, were assessed.

**METHODS**

**Study design and population**

Patients visiting the NPSLE clinic of the Leiden University Medical Center between 2007 and 2019 with the clinical diagnosis of SLE and signed informed consent were included in this study. The NPSLE clinic is a tertiary referral center in which patients with neuropsychiatric (NP) symptoms, potentially caused by SLE, are assessed multidisciplinary. This evaluation process has been described in detail previously. In short, NP symptoms attributed to SLE by multidisciplinary consensus requiring immunosuppressive or anticoagulant treatment are classified as ‘major NPSLE’. NP symptoms not attributed to SLE, mild NP symptoms that do not require additional treatment other than symptomatic treatment or NP symptoms due to other causes are classified as minor/non-NPSLE. Patients with major NPSLE are further classified as having an ischaemic, inflammatory or combined (both ischaemic and inflammatory) phenotype, based on the suspected pathogenetic mechanism. Major NPSLE diagnoses are classified according to the 1999 American College of Rheumatology (ACR) case definitions for NPSLE syndromes. Online supplemental figure 1 depicts the inclusion procedure.

**Patient and public involvement**

No patients were involved in the concept or design of this study.

**Patient characteristics**

Demographic and clinical patient characteristics were collected from electronic medical files of the visit to the NPSLE clinic: age, sex, smoking status, body mass index, 1997 SLE classification criteria, SLE duration, SLEDAI-2K, Systemic Lupus International Collaborating Clinic/ACR Damage Index, presence and phenotype of NPSLE and medication use. Active nephritis was defined as haematuria, proteinuria, urinary casts or pyuria according to the SLEDAI-2K. The presence of active arthritis was established during physical assessment. Serum samples from each participant were collected at time of visit to the NPSLE clinic. In some patients with inflammatory NPSLE, immunosuppressive treatment was already initiated at this time point (median treatment duration: 1 month). Details of routine laboratory assessment are provided in online supplemental file II.

**Assessment of anti-PTMs**

**Generation of antigens**

Modified proteins and their corresponding control non-modified protein were produced by either enzymatic or chemical reactions as previously described with some adaptations. For more details, see online supplemental file II.

**Detection of anti-PTM IgG antibodies by ELISA**

Modified fetal calf serum (FCS) and non-modified FCS were coated at 10 µg/mL in 0.1 M carbonate–bicarbonate buffer pH 9.6 on Nunc Maxisorp plates (430341, Thermofisher) overnight at 4°C. In between each step, plates were washed with Phosphate Buffered Saline (PBS) overnight (P1379, Sigma). After washing, wells were incubated with serum at a 1/50 dilution in PBS/0.05% Tween (P1379, Sigma). For each PTM, a standard of human IgG-HRP (P0214, Dako) diluted in PTB and incubated at 4°C for 3.5 hours. After the final wash, HRP enzyme activity was visualised using ABTS (A1888, Merck) with
0.05% H2O2 (107209, Merck) and absorbance at 415 nm was read using a microplate reader (Bio-Rad). Serum samples of 108 healthy controls (HCs) from the Leiden area were also tested.\textsuperscript{32, 33} Absorbance was transformed to arbitrary units per millilitre (aU/mL) using a corresponding standard line for each PTM. Background aU/mL of FCS was subtracted from the aU/mL signal on FCS-PTM to analyse specific anti-PTM reactivity. Negative outcomes were changed to 0. Positivity for specific anti-PTM Abs was defined as a value larger than the mean plus two times the SD in the HCs. HCs with a value ≥10× the mean were excluded in calculating the cut-off.

Additionally, sera of 54 patients with NPSLE at their second visit (<2 years after first visit) were analysed for anti-PTM Ab reactivity.

### Brain volume

Brain volume measurements were available for 182 patients visiting the NPSLE clinic between 2007 and 2015. An extensive description thereof has been published previously.\textsuperscript{34, 35} In short, white matter volume (WMV), grey matter volume, white matter hyperintensity volume and total brain volume (TBV) were assessed using the CAT12 toolbox from the statistical parametric mapping software and the Lesion Segmentation Toolbox V.2.0.15.\textsuperscript{36}

### Statistical analysis

Differences in levels of anti-PTM Abs between HCs, patients with SLE and specific SLE manifestations were assessed using the Mann-Whitney test and X\textsuperscript{2} test. Median, median difference and 95% CIs were calculated using quantile regression. Further analyses were only performed if anti-PTM Ab positivity between HCs and SLE differed by at least a factor of two. Spearman rank analyses were used to assess correlation between anti-PTM Ab levels and all continuous clinical variables (including brain volumes). Point-biserial correlations were used to assess correlation between the level of anti-PTM Abs (continuous) and other Abs (dichotomous). As anti-PTM Ab level was non-normally distributed, the levels were natural log transformed for the point-biserial correlations. Kruskal-Wallis test was used to compare level of anti-PTM Abs in patients with different NPSLE phenotypes. Wilcoxon signed-rank test was used to compare anti-PTM Ab level at baseline versus follow-up. P values of ≤0.05 were considered significant.

All statistical analyses were performed using STATA statistical software V.16.

### RESULTS

#### Study cohort

In total, 349 patients with SLE were included in this study: 87% female and mean age 43.7±13.4 years. At time of enrolment, median disease duration was 4 years (IQR: 1–13) and median disease activity (SLEDAI-2K) was four (IQR: 2–8) (table 1). The most common ACR 1997 criteria were anti-nuclear Abs (ANA) positivity ever (97%), immunological disorder (76%) and non-erosive arthritis (59%). Major NPSLE was diagnosed in 104 patients (30%), of which 51 patients had an inflammatory, 28 patients an ischaemic and 25 patients a combined phenotype. NPSLE syndromes (1999 ACR case

Results are presented as n (%) or median (IQR).  
*Missing data nuclear antibodies: ANA+anti-dsDNA: n=1, other: n=2; antiphospholipid antibodies: anti-β2-glycoprotein n=79, lupus anticoagulant: n=5, aCl=1; complement factors: n=2, inflammation: n=2. Percentages are given for the number of positive patients divided by the number of patients tested.

ANA, anti-nuclear antibodies; anti-dsDNA, anti-double-stranded DNA; anti-RNP, anti-ribonucleoprotein; anti-Smith, anti-Smith; anti-SSA/B, anti-Sjögren’s syndrome-related antigen A/B autoantibodies; CRP, C-reactive protein; ENA, extractable nuclear antigen antibodies; ESR, erythrocyte sedimentation rate.

Next, we sought to investigate whether these increased anti-PTM Abs correlated with clinical and serological markers (figure 1A–C and online supplemental table 2). Anti-MAA and anti-AGE both negatively correlated with levels of complement factors C3 and C4 (p≤0.002) and correlated positively with erythrocyte sedimentation rate (ESR) (p<0.001). ANA (p=0.02/0.03), anti-double-stranded DNA (p≤0.005) and anti-Smith (p=0.02). Anti-MAA negatively correlated with disease duration (p=0.03) and showed positive correlations with disease activity (p=0.03) and anti-cardiolipin (p=0.0003). Compared with anti-MAA, anti-AGE correlated slightly stronger with disease activity (p=0.001). All correlations found were modest (correlation coefficients ≤0.30). Anti-CarP only correlated significantly with age (p=0.01). There was no significant difference in anti-PTM Ab levels between patients with and without immunosuppressive treatment.

*Statistically significant difference between patients with SLE and healthy controls (p<0.0001).

AGE, advanced glycation end-product; AL, acetylated protein; aU/mL, arbitrary units per millilitre; CarP, carbamylated protein; Cit, citrullinated protein; MAA, malondialdehyde–acetaldehyde adduct; NT, nitrated protein.
Anti-MAA and anti-CarP are more common in major NPSLE than in other SLE organ manifestations

Levels and positivity for different anti-PTM Abs were compared between patients with and without specific SLE manifestations (table 4 and figure 2A–C). As our cohort comprises patients visiting an expertise center for NPSLE, we primarily focused on this manifestation. Patients with major NPSLE more frequently harboured anti-MAA Abs (39% vs 24%, p=0.01) and anti-CarP Abs (20% vs 11%, p=0.04) compared with patients without major NPSLE, whereas the prevalence of anti-AGE Abs did not differ as clearly (23% vs 16%, p=0.13). In our cohort, for patients with active nephritis or active arthritis, differences in anti-PTM Ab positivity were less pronounced. Associations between the different anti-PTM Abs and ever having major organ manifestations are presented in online supplemental table 3.

Anti-PTM Abs are similarly present in different major NPSLE phenotypes

As NPSLE has different pathophysiological origins, levels and positivity for different anti-PTM Abs were compared within NPSLE subgroups. We found that these levels and positivity were relatively similar among different NPSLE phenotypes (table 4). This may reflect the fact that NPSLE is a multifaceted disease with involvement of various organs and systems.
specific phenotypes of major NPSLE (see online supplemental table 4). Patients with a combined NPSLE phenotype showed the most anti-PTM Ab positivity (anti-MAA=40%, anti-AGE=28%, anti-CarP=32%), followed by patients with an inflammatory phenotype (41%, 27% and 14%, respectively) and an ischaemic phenotype (36%, 11% and 21%, respectively). These differences were not statistically significant. In addition, no difference was observed in the presence of anti-PTM Abs between patients with inflammatory NPSLE who did and did not initiate immunosuppressive treatment prior to the clinic visit.

**Brain volume and anti-PTM Abs**

Previous analyses were based on the distinction between major and minor NP involvement, of which the diagnosis was based on multidisciplinary assessment. As this has the risk for phenotypical misclassification, we sought to study the correlation between anti-PTM Abs and an objective marker of central nervous system (CNS) involvement in SLE. For 182 patients (52%), assessment of brain volumes was available (see online supplemental table 5). The strongest correlations were between anti-MAA and WMV and TBV (Spearman ρ=–0.20 and –0.18; both p<0.02) and anti-AGE and WMV and TBV (both Spearman ρ=–0.16; both p=0.03). Anti-CarP showed a significant association with white matter hyperintensity volume (Spearman ρ=0.19, p=0.03).

**Longitudinal study comparing anti-PTM Ab responses over time**

In order to study anti-PTM Abs over time, serum samples from 54 patients, that were taken within 2 years after the

Figure 2  Levels of (A) anti-MAA, (B) anti-AGE, and (C) anti-CarP IgG in patients with (n=104) and without (n=245) major NPSLE. Reactivity was determined using ELISA and cut-off was calculated using mean plus two times the SD of the healthy controls (dashed line), as described in the Methods section. Reactivity is depicted as arbitrary units per millilitre (aU/mL). AGE, advanced glycation end-product; CarP, carbamylated protein; MAA, malondialdehyde–acetaldehyde adduct; NPSLE, neuropsychiatric systemic lupus erythematosus.
first visit, were analysed. Levels of anti-MAA, anti-AGE and anti-CarP Abs generally showed a decrease (Figure 3A–C). This decrease was significant for anti-MAA and anti-AGE ($p \leq 0.0001$), but not for anti-CarP ($p=0.20$). Change in anti-MAA and anti-AGE Ab levels associated with change in SLEDAI-2K (both Spearman $\rho$: 0.29 and 0.28, $p=0.04$), respectively, but change in anti-CarP Ab level did not (Spearman $\rho$: 0.11, $p=0.41$).

**DISCUSSION**

We hypothesised that in SLE, there is generation of PTMs on relevant antigens and that the presence of anti-PTM autoantibodies may be associated with clinical presentation and/or disease activity. Therefore, we investigated the presence of Abs against six different PTMs on the same antigen backbone (FCS). We indeed observed that breaking of tolerance in SLE results in production of Abs against the PTMs, predominantly MAA, AGE and CarP, and less pronounced against Cit, AL and NT. Furthermore, anti-MAA Abs and anti-AGE Abs associated with markers of inflammation. Finally, we searched for Abs specific for NPSLE and observed that anti-MAA and anti-CarP Abs associated with major NPSLE.

Many different PTMs occur in both health and disease. Carbamylation and citrullination have been identified in patients with RA and Ab responses against these PTMs are nowadays used as a clinical measure. While it is currently unknown why a subset of the patients produce anti-PTM Abs, there is substantial insight into the processes that drive the PTM of proteins. Inflammation and oxidative stress can lead to formation of reactive oxygen species (ROS) or induction of enzymes, which may lead to the formation of PTMs. ROS can lead to malondialdehyde (MDA) following peroxidation of lipids from, for instance, cell membranes leading to MAA modification. Additionally, the ROS peroxynitrite is the reactive compound for nitration. Citrullination is the peptidyl arginine deiminase enzyme-mediated conversion of arginine. During carbamylation, the conversion of lysine into homocitrulline is driven by a chemical reaction with cyanate, a compound in equilibrium with urea and induced by smoking and inflammation. Excessive glycation is also a response to oxidative stress and inflammation leading to AGEs. AGEs in turn bind to AGE receptor leading to the perpetuation of inflammation. Excessive acetylation is a result of dysregulation of acetylation and deacetylation pathways. Taken together, specific PTMs are a consequence of inflammation and oxidative stress. It is therefore well possible that these modifications occur in patients with SLE in which widespread inflammation is
going on. We previously observed that the PTM carba-
methylolation is present in the joint of patients with RA, but
also in the joint of HCs, while the anti-CarP Abs are only
found in a subset of patients with RA.45 Why only a subset
of patients with RA and SLE produce such anti-PTM
Abs is still unknown. In our study, we demonstrated
that three anti-PTM Abs are more prevalent in patients
with SLE than in HCs, in increasing prevalence: anti-
CarP, anti-AGE and anti-MAA. As only three out of six
tested anti-PTMs showed increased reactivity, a specific
induction process is implied. MAA, AGE and CarP are all
modifications that occur on the lysine residue. However,
AL is also a modification of lysine residue, but no differ-
eence in reactivity between patients with SLE and HCs was
observed there. Whether a specific underlying patholog-
ical mechanism for reactivity against these three PTMs
exists needs to be further investigated. As patients with
SLE are known for their global loss of self-tolerance, it is
plausible that PTMs, that are persistently or abundantly
present, are targeted. However, other factors, such as
 genetics and environmental triggers, might play a role
in breaking tolerance towards PTMs.44 45 In order to
understand specific anti-PTM reactivities, the location
of specific PTMs in different organ tissues in patients
with SLE needs to be evaluated. Furthermore, studies
on monoclonal Abs obtained from patients with SLE are
required to further pinpoint specific reactivity.

The three notable anti-PTM Ab responses have been
studied to some degree in SLE before. Anti-CarP Abs,
prevalent in 8%–53% of patients with SLE in other studies,
have been associated with articular involvement, joint
damage and disease activity (SLEDAI).13 16 17 Our study
was unable to confirm these findings, possibly because of
the low number of patients with arthritis in our cohort.
We can however exclude that the observed association
between the presence of certain anti-PTM Abs and major
NPSLE is driven by the association between anti-PTM Abs
and arthritis and the concurrent presence of arthritis and
major NPSLE. An increase of anti-CarP Abs was observed
in patients with major NPSLE, but the clinical meaning
of this remains to be elucidated as limited correlation with
other clinical markers was observed. Anti-AGE Abs have
not been studied previously in SLE. However, increased
amounts of AGEs have been identified in skin tissue of
patients with SLE and increased AGEs in blood plasma
are described, which correlated with disease activity.46 We
demonstrated an association between anti-AGE Abs and
different markers of systemic inflammation. In our study,
anti-MAA associated most clearly with different markers
of inflammation. Few previous studies have investigated
the role of MDA, the unstable predecessor of MAA in
SLE. One study demonstrated that anti-MDA IgG posi-
tively correlated with disease activity, ESR and C-
reactive protein and negatively correlated with complement
factors.15 16 This is in line with the results of our study. In
this same study, an association with renal involvement was
found, using a different definition for active nephritis
(proteinuria >5 g per day or greater than 3 by dipstick,
and/or cellular casts), whereas our study demonstrated
an association with major NPSLE, a disease for which
virtually no biomarker exists.

Several Abs have been suggested as biomarker for
NPSLE.37 In particular, anti-ribosomal P and anti-N-
methyl-D-aspartate receptor Abs have been implicated
in the pathogenesis of NPSLE, although their exact role
remains inconclusive and their clinical value limited.48–50
It is thought that breaches of the neuroimmune inter-
face (among others, the blood–brain barrier) might
enable neuropathic Abs in the serum of patients to
enter the CNS.49 Interestingly, we demonstrated that
several anti-PTM Abs are more prevalent in patients
with major NPSLE. Discrimination between the pres-
ence and absence of NPSLE is important, as it influences
treatment. The diagnosis is based on multiple clinical
factors, and the presence or absence of anti-PTM Abs
could give further direction. Additional studies need to
clarify whether anti-PTM responses are specific enough
for NPSLE or should be interpreted as part of a series
of markers to point towards specific subgroups. The
observed association between anti-PTM Abs and NPSLE
is supported by the correlation between specific anti-PTM
Abs and white matter and white matter hyperintensity
brain volume, objective measures of CNS involvement
linked to NPSLE. MAA has previously been linked to
brain injury and neurodegenerative diseases.51 52 Further-
more, in ageing individuals, increased levels of MDA are
seen in the temporal lobes, occipital lobes and hippo-
campus, underlying the potential relevance of anti-MAA
Abs.36 We demonstrated that all three anti-PTM Abs
(anti-MAA, anti-AGE and anti-CarP) showed a decrease
in reactivity over time, of which anti-MAA and anti-AGE
correlated with disease activity. To further uncover the
role of anti-PTM Abs in NPSLE, future studies should
assess the presence of anti-PTMs in cerebrospinal fluid.

Our study has several strengths: we used a standardised
controlled ELISA set-up with one antigen backbone for
each of the PTMs and a well-defined cohort of patients
with SLE and specifically NPSLE. There are also several
limitations to our study. A relatively large number of patients
were negative or weakly positive for ANA at inclusion, which
was tested at a dilution of 1:40. Therefore, we repeated the
analyses in the patients positive for ANA (see online supple-
mental file III), which led to similar results as the main
analyses. Furthermore, as this study cohort is part of a
tertiary referral for NPSLE, other clinical subsets (such
as arthritis) are less prevalent. In this exploratory study
within a well-defined cohort, we found anti-PTM Abs
as potential biomarker for NPSLE and now additional
studies need to be performed to determine the discrimi-
native value of anti-PTM in different clinical settings, such
as the outpatient clinic of a non-academic hospital. In
addition, the clinical correlations identified in this study
were modest and need further investigation. Lastly, the
diagnosis of major NPSLE is made on clinical grounds.
Although this is a clinically relevant phenotype, there

8 Monahan RC, et al. RMD Open 2022;8:e002079. doi:10.1136/rmdopen-2021-002079
still might be different underlying biological processes. Therefore, we used an objective marker (brain volumes) for CNS involvement and found an association with anti-PTM Abs.

In conclusion, we identified three anti-PTM Abs (anti-MAA, anti-AGE and anti-CarP) that are present more frequently in patients with SLE, of which anti-MAA and anti-AGE correlate with measurements of systemic inflammation. Furthermore, several anti-PTM Abs (anti-MAA and anti-CarP) were more prevalent in patients with major NPSLE, a disease manifestation currently lacking a suitable biomarker. In addition, all three anti-PTM Abs also correlated with brain volumes. Further research should confirm the role of anti-PTM Abs as well as its discriminative value for (NP)SLE.

Acknowledgements We thank our colleagues from the Department of Radiology, especially Jeroen de Bresser and Francesca Ilesco, for the data on brain volumes.

Contributors All authors were involved in the design and interpretation of the study. (NP)SLE data collection and statistical analyses were performed by RCM under the supervision of GMS-B. TWJH and MK. Anti-PTM antibody analyses and interpretation were performed by MvDdB and NBV under the supervision of LAT. LAT is the guarantor for this study.

Funding LAT has received funding from the European Research Council (ERC) under the European Union’s Horizon 2020 research and innovation programme (grant agreement no. 724517).

Competing interests TWJH and LAT are listed as inventors on a patent describing the methods to detect anti-CarP antibodies.

Patient consent for publication Obtained.

Ethics approval This study involves human participants and was approved by the Medical Ethical Committee of Leiden-The Hague-Delft (reference number: B18.040). Participants gave informed consent to participate in the study before taking part.

Provenance and peer review Not commissioned; externally peer reviewed.
